Lesson 13 Summary

Let's think about the linear equation $2x - 4y = 12$. If we know $(0, -3)$ is a solution to the equation, then we also know $(0, -3)$ is a point on the graph of the equation. Since this point is on the y-axis, we also know that it is the vertical intercept of the graph. But what about the coordinate of the horizontal intercept, when $y = 0$? Well, we can use the equation to figure it out.

$$2x - 4y = 12$$
$$2x - 4(0) = 12$$
$$\frac{2x}{2} = \frac{12}{2}$$
$$x = 6$$

Since $x = 6$ when $y = 0$, we know the point $(6, 0)$ is on the graph of the line. No matter the form a linear equation comes in, we can always find solutions to the equation by starting with one value and then solving for the other value.

* Always look for the most efficient way to solve for a variable.

* Linear Equations can also be in written in standard form $Ax + By = C$ where $A, B, \text{ and } C$ are numbers. You can always rewrite this equation in $y = mx + b$ form.

Ex: $\frac{1}{2}x + 3y = 12$ (Standard form)

- $\frac{1}{2}x$ (move $x$ to other side - take it's opposite)

- $\frac{3y}{3} = -\frac{x}{3} + 12$

- $y = -\frac{1}{3}x + 4$

- $-\frac{1}{3}x = -\frac{1}{3}x$
